Office of Evidence Based Practice (EBP) – Critically Appraised Topic (CAT): Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)

Specific Care Question

Are criteria necessary to stop contact precautions (CP) in patients diagnosed with ESBL?

Recommendations Based on Current Literature (Best Evidence) Only

A conditional recommendation is made for ceasing the use of contact precautions (CP) for patients diagnosed with ESBL based on expert review of current literature by the Department of EBP. The overall certainty in the evidence is very low^a. The data reported in four studies are incorporated into this report. Based on the study findings, transmission rates of ESBL did not increase significantly after organizations supplanted CP with the use of standard precautions (SP), when caring for patients diagnosed with ESBL.

Literature Summary

Background. ESBL is an enzyme found in some strains of bacteria which have the ability to break down and destroy beta-lactam antibiotics (Centers for Disease Control and Prevention, 2019). ESBL was initially identified as a Hospital Acquired Infection (HAI) due to outbreaks within intensive care units however, the epidemiology has changed to include both HAI and community onset infections (Centers for Disease Control and Prevention, 2019; van Hout et al., 2020). As this disease is spread through the contact of infected human or animal fecal material, hospitalized patients have historically been isolated with CP for each admission after being diagnosed with this disease. However, new literature suggests that patients do not need to be placed in CP. This review will summarize identified literature to answer the specific care question.

In addition to the literature review, an informal city-wide survey ($N = 12$), of the Association for professionals in Infection Control and Epidemiology members (Y. Ballam, personal communication, February 3, 2020), identified that isolation practice is variable when caring for this patient population:

- four organizations isolate with CP for duration of stay,
- three organizations use one or two negative ESBL cultures to determine if CP can be removed,
- two organizations employ CP each time the patient is admitted,
- one organization employs CP for six months from diagnosis,
- one organization uses CP if the patient has an active uncontained infection, and
- one organization does not isolate patients diagnosed with ESBL.

Study characteristics. The search for suitable studies was completed on February 3, 2020. Y. Ballam, BS, CIC; R. Mott, MSN, FNP-BC, CIC, APRN; and S. McCullough-Culer, MPH, BSN, RN, CIC reviewed the 23 titles and/or abstracts^b found in the search. No guidelines were found to answer the question, but nine single studies were believed to answer the question. After an in-depth review of the nine articles^c, four answered the question. All four studies (Jalalzai et al., 2018; Renaudin et al., 2017; Thompson, Teter, & Atrubin, 2020; Tschudin-Sutter et al., 2016) employed a before and after cohort methodology (see Figure 1) to measure the effect of discontinuing CP for patients with a history of ESBL.

Summary by Outcome

Incidence of HAI with ESBL. Four studies (Jalalzai et al., 2018; Marra, Edmond, Schweizer, Ryan, & Diekema, 2018; Renaudin et al., 2017; Thompson et al., 2020; Tschudin-Sutter et al., 2016) reported ESBL transmission in two ways: Incidence rates of health care associated ESBL infection (Jalalzai et al., 2018; Thompson et al., 2020; Tschudin-Sutter et al., 2016) and incidence density rates (Renaudin et al., 2017). The total population for the included studies, nor the reported study findings, could not be pooled due to how the data was reported (a) two studies (Jalalzai et al., 2018; Renaudin et al., 2017) reported the sample size as patients, (b) Tschudin-Sutter et al. (2016) reported only contact and index sample sizes, and (c) Thompson et al. (2020) described the sample size as laboratory specimens.

Jalalzai et al. (2018) reported an insignificant finding ($p = 0.94$) that ICU acquired ESBL infections accounted for 5.2% and 5.5%, before and after, ceasing active surveillance ESBL cultures. Renaudin et al. (2017) reported a significant ($p = .004$) nonsuperiority incidence density finding for ESBL in the ICU before and after ceasing CP 2.7, 95% CI [1.78, 3.62] and 2.06, 95% CI [1.27, 2.86] per 1,000 patient days, respectively. Thompson et al.

Office of Evidence Based Practice (EBP) – Critically Appraised Topic (CAT): Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)

(2020) described a significant decrease ($p = .022$) when comparing health care-associated ESBL rates before and after eliminating CP 3.71 per 10,000 patient days versus 3.00 per 10,000 patient days, respectively. Tschudin-Sutter et al. (2016) reported a transmission rate of 2.6% after CP were removed for patients with ESBL. These findings indicate that removal of CP in patients diagnosed with ESBL does not significantly ($p = .052$) increase transmission rates when SP are followed.

Certainty of the evidence for HAI with ESBL. The certainty of the body of evidence is based on four factors: within-study risk of bias, consistency among studies, directness of evidence, and precision of effect estimates. The body of evidence was assessed to have very serious risk of bias, and very serious inconsistency. The risk of bias was assessed to be very serious as the four included studies employed a cohort methodology which may have influenced the study findings through uncontrolled confounding variables. The assessment of very serious inconsistency was attributed to the body of literature as different populations and outcome measures were reported.

Identification of Studies

Search Strategy and Results (see Figure 1)

Search: (((("beta-Lactamases"[MeSH] OR "beta-Lactam Resistance"[Mesh]) AND ("Enterobacteriaceae Infections"[Mesh] OR "Enterobacteriaceae"[MeSH])) OR "Drug Resistance, Multiple, Bacterial" [mesh] OR extended-spectrum β -lactamase OR extended-spectrum beta-lactamases OR ESBL-producing E. coli OR ESBL OR extended-spectrum β -lactamase (ESBL) producing organisms OR extended-spectrum β -lactamase) AND (((screen OR screening OR Isolation OR "Transmission-based precautions" OR "contact precautions" OR "infection control" OR effectiveness[tiab]) AND (Cessation OR discontinue OR discontinuation OR discontinue)) OR (Return to Standard Precautions) OR "universal contact precautions")

Studies Included in this Review

Citation	Study Type
Jalalzai et al. (2018)	Before/After cohort
Renaudin et al. (2017)	Before/After cohort
Tschudin-Sutter et al. (2016)	Before/After cohort
Thompson et al. (2020)	Before/After cohort

Studies Not Included in this Review with Exclusion Rationale

Citation	Reason for exclusion
Johnson and Quach (2017)	Narrative review
Marra et al. (2018)	Systematic review which reported the findings from Tschudin-Sutter et al. (2016) as this article is reported as a single study this review was excluded from this report.
Metan et al. (2017)	Letter to the editor
Prevel et al. (2019)	Titled as a systematic review but it was a narrative review
van den Bijllaardt et al. (2018)	Studied the performance of ESBL PCR as a screening assay for ESBL carriage

Methods Used for Appraisal and Synthesis

^a[The GRADEpro Guideline Development Tool \(GDT\)](#) is the tool used grade the overall body of literature for this analysis.

^bRayyan is a web-based software used for the initial screening of titles and / or abstracts for this analysis (Ouzzani, Hammady, Fedorowicz & Elmagarmid, 2017).

^cReview Manager (Higgins & Green, 2011) is a Cochrane Collaborative computer program used to assess the study characteristics as well as the risk of bias and create the forest plots found in this analysis.

Office of Evidence Based Practice (EBP) – Critically Appraised Topic (CAT): Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)

^dThe Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram depicts the process in which literature is searched, screened, and eligibility criteria is applied (Moher, Liberati, Tetzlaff, & Altman, 2009).

**Office of Evidence Based Practice (EBP) – Critically Appraised Topic (CAT):
Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)**

Patient outcomes

- In-ICU death was similar during the two periods, ICU length of stay, hospital length of stay and hospital mortality rates did not significantly differ.

	All patients <i>n</i> = 1069	ASC period <i>n</i> = 524	No-ASC period <i>n</i> = 545	<i>p</i> value
ICU median length of stay (IQR), days	6 (4-11)	6 (4-11)	6(4-11)	.82
Hospital median length of stay (IQR), days	16 (8-27)	16 (9-27)	16 (8-29)	.89
In-ICU mortality, <i>n</i> (%)	220 (20.6)	101 (19.3)	119 (21.8)	.30
Hospital mortality, <i>n</i> (%)	272 (25.4)	130 (24.8)	142 (26.1)	.64

- The cumulative incidence of ICU-acquired ESBL-E infections did not differ between periods
- Overall carbapenem exposure in patients with no ICU-acquired ESBL-E infection decreased between ASC period and no-ASC period (75 versus 62 carbapenem-days per 1000 patients, respectively, *p* = .01)

Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)**

Interventions	<p>Group 1: CP for ESBL-positive laboratory results Group 2: No CP for ESBL-positive (only) laboratory results</p>																																														
Outcomes	<p>Primary outcome:</p> <ul style="list-style-type: none"> Incidence of healthcare acquired infection (HAI) with ESBL-positive laboratory results* <p>Secondary outcome:</p> <ul style="list-style-type: none"> Number of patients not being placed in CP <p>Safety outcome:</p> <ul style="list-style-type: none"> Not reported <p>*Outcomes of interest to the CMH CAT development team</p>																																														
Results	<ul style="list-style-type: none"> Reported 387 cases of HAI with ESBL infections during the entire study time frame. Pooled ESBL incidence density rate decreased from 3.71 per 10,000 patient days to 3.0 per 10,000 patient days. Documented HAI associated ESBL infection after discontinuation of CP was 25% Lower compared with the baseline period ($p < .001$). The Durbin-Watson statistic confirmed no autocorrelation (Durbin-Watson = 2.11) and the Dickey-Fuller unit root test confirmed stationarity of the outcome variable (tau, -6.54; $p < .001$) for the model. Approximately 378 patients with ESBL-positive organisms were not placed in isolation. <table border="1" data-bbox="583 690 2003 1010"> <thead> <tr> <th rowspan="2"></th> <th colspan="3">Pre-Intervention (January 2014 - November 2015)</th> <th colspan="3">Post-Intervention (December 2015 - August 2017)</th> <th rowspan="2"><i>p</i> value</th> </tr> <tr> <th>Number</th> <th>Denominator</th> <th>Rate</th> <th>Number</th> <th>Denominator</th> <th>Rate</th> </tr> </thead> <tbody> <tr> <td>Community Prevalence Rate (per 10,000 patient encounters)</td> <td>370</td> <td>282,145</td> <td>13.114</td> <td>516</td> <td>299,983</td> <td>17.201</td> <td>.001</td> </tr> <tr> <td>HAI incidence rate [all organisms] (per 10,000 patient days)</td> <td>221</td> <td>595,336</td> <td>3.712</td> <td>166</td> <td>553,748</td> <td>2.998</td> <td><.001</td> </tr> <tr> <td>Community Prevalence Rate (per 10,000 patient encounters)</td> <td>370</td> <td>282,145</td> <td>13.114</td> <td>516</td> <td>299,983</td> <td>17.201</td> <td>.001</td> </tr> <tr> <td>HAI incidence rate [all organisms] (per 10,000 patient days)</td> <td>221</td> <td>595,336</td> <td>3.712</td> <td>166</td> <td>553,748</td> <td>2.998</td> <td><.001</td> </tr> </tbody> </table>		Pre-Intervention (January 2014 - November 2015)			Post-Intervention (December 2015 - August 2017)			<i>p</i> value	Number	Denominator	Rate	Number	Denominator	Rate	Community Prevalence Rate (per 10,000 patient encounters)	370	282,145	13.114	516	299,983	17.201	.001	HAI incidence rate [all organisms] (per 10,000 patient days)	221	595,336	3.712	166	553,748	2.998	<.001	Community Prevalence Rate (per 10,000 patient encounters)	370	282,145	13.114	516	299,983	17.201	.001	HAI incidence rate [all organisms] (per 10,000 patient days)	221	595,336	3.712	166	553,748	2.998	<.001

Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)**

Tschudin-Sutter et al. (2016)

<i>Characteristics of Study</i>	
Methods	Cohort, Pre and Post Intervention
Participants	<p>Participants: Hospitalized patients and long-term care facility patients Setting: University Hospital Basel (UHB) and affiliated long-term care center Felix Platter Hospital (FPH), Basel, Switzerland Number enrolled into study: $N = 442$</p> <ul style="list-style-type: none"> • Group 1, Index Patients: $n = 211$ <ul style="list-style-type: none"> • UHB Patients: $n = 178$ • FPH Patients: $n = 33$ • Group 2, Contact Patients: $n = 231$ <ul style="list-style-type: none"> • UHB Patients: $n = 151$ • FPH Patients: $n = 80$ <p>Number completed: $N = 442$</p> <ul style="list-style-type: none"> • Group 1: $n = 211$ • Group 2: $n = 231$ <p>Gender, males: Not reported Race / ethnicity or nationality (as defined by researchers): <ul style="list-style-type: none"> • The study occurred in Switzerland. The authors did not identify race or ethnicity of the participants. Age: Not reported Inclusion criteria: Not reported Exclusion criteria: Not reported Covariates identified: Not reported</p>
Interventions	<p>Both: UHB and FPH abandoned routine CP for patients with extended-spectrum β-lactamase (ESBL)-producing <i>Escherichia coli</i> (<i>E. coli</i>)</p> <ul style="list-style-type: none"> • Group 1: Patients colonized or infected with an ESBL-producing <i>E. coli</i> • Group 2: Patients hospitalized for at least 24 hours in the same room as an index patient <ul style="list-style-type: none"> ○ Screened for ESBL-producing <i>E. coli</i> after a median contact time of 4 days at UHB and 15 days at FPH

**Office of Evidence Based Practice (EBP) – Critically Appraised Topic (CAT):
Isolation Needs for Patients with extended-spectrum β -lactamase (ESBL)**

<p align="center">Outcomes</p>	<p>Primary outcome:</p> <ul style="list-style-type: none"> • ESBL- producing <i>E. coli</i> transmission rates* <p>Secondary outcome:</p> <ul style="list-style-type: none"> • Contact time* <p>Safety outcome:</p> <ul style="list-style-type: none"> • Not reported <p>*Outcomes of interest to the CMH CAT development team</p>
<p align="center">Results</p>	<ul style="list-style-type: none"> • After discontinuing contact isolation precautions in shared hospital rooms where a patient with ESBL-producing <i>E.coli</i> (index patient) was exposed to a patient without the infection (contact patient) for at least 24 hours, transmission rates were 2.6% and 8.8% at an acute-care (UHB) and a geriatric/rehabilitation hospital (FPH), respectively. • With the use of CP, the reported transmission rates were 1.5% at UHB, and 6.5% for similar settings to FPH (previous transmission rates for FPH specifically were not reported). • Exposure to an index patient for >5 days was associated with increased odds for transmission $OR = 10.18$, 95% CI [1.28, 80.91], $p = .028$
