## **Office of Evidence Based Practice (EBP) – Critically Appraised Topic: Starting Enteral Feedings after Medical NEC**

### **Specific Care Question**

For the patient in the NICU with medical necrotizing enterocolitis (mNEC) when is the optimal time to restart enteral feedings?

### **Recommendations from the XXXXX Team**

*No recommendation can be made on the timing of the re-initiation of enteral feedings after Stage IIa or IIb NEC. Three cohort studies are included, that show no difference in NEC recurrence or intestinal stricture if feedings are restarted early, and catheter related sepsis is lower when feedings are restarted early. However, the definition of early and late refeeding varied among the studies, which makes the studies inconsistent, and the time frame over which data was collected is wide. Other changes in neonatal care may have occurred to influence the outcomes.*

*When there is a lack of scientific evidence, standard work should be developed, implemented, and monitored.*

### **Literature Summary**

**Background.** Necrotizing enterocolitis is a condition that affects premature infants. In its most severe form, NEC causes severe inflammation and necrosis of the intestinal mucosa (Kim, 2019, Shenk 2019). It also presents in less severe forms. Medical NEC (mNEC) is when surgery is not required. A staging system, known as Bell staging, has been developed to describe the symptoms:

Name	Bell Stage	Symptoms
Suspected	Stage I	Emesis, abdominal distension, bloody stool
Proven	Stage II a	All the above, plus abdominal tenderness and lack of bowel sounds
Proven	Stage IIb	All the above, plus abdominal cellulitis
Advanced	Stage III	All the above, plus hypotension, pH imbalance, bradycardia, neutropenia

*Note: from (Kim, 2019; Shenk et al., 2019)*

Necrotizing enterocolitis is managed by stopping enteral feedings, initiating antibiotics, and continuing other supportive treatment, such as temperature regulation (Hock et al., 2018). There is a lack of standardization of when to re-start enteral feedings after a mNEC event. From a survey sent to 34 Intensive Care Nurseries ( $n = 22$  responses) participating in the Children’s Hospitals Neonatal Consortium (O’Donnell et al., 2019):

- 60% (13/22)- began enteral feeding on the day after antibiotics were completed
- 23% (5/22)- began enteral feeding on the day of discontinuation of antibiotics
- 18% (4/22-) starting feeds after resolution of pneumatosis and the return of bowel function

It is unknown if early or late reinitiation in feeding plays a role in NEC recurrence, time to full feeds, growth, or hospital length of stay. In the calendar year 2017-2018, the NICU at Children’s Mercy Kansas City discharged 13 patients with mNEC (Younger, 2019). Variation of timing of the restart of enteral feeds after mNEC is unknown.

The goal of the NICU is to standardize the initiation of enteral feedings after mNEC and to identify process points for feeding infants after mNEC to decrease patient important outcomes such as NEC recurrence, time to full feeds and hospital length of stay. This review will summarize identified literature to answer the specific care question.

## **Office of Evidence Based Practice (EBP) – Critically Appraised Topic: Starting Enteral Feedings after Medical NEC**

**Study characteristics.** The search for suitable studies was completed on December 6, 2019. A. Khmour, MD and Denise Smith, RN, NNP-BC reviewed the 105 titles and/or abstracts found in the search and identified<sup>b</sup> 10 single studies believed to answer the question. A systematic review/meta-analysis was identified by ancestry search and led to two additional<sup>c</sup> studies that answered the question. After an in-depth review of the fourteen articles<sup>c</sup>, four answered the question (see Figure 1).

**Optimal time to start feedings after mNEC.** Hock et al. (2018) is a systematic review/meta-analysis of two cohort studies that evaluated the timing of re-initiation of enteral feedings after mNEC. The two cohort studies are Bohnhorst et al. (2003) and Brotschi, Baenziger, Frey, Bucher, and Ersch (2009). Hock et al. (2018) reported on the outcomes (a) NEC recurrence, (b) catheter related sepsis, and (c) occurrence of intestinal stricture. Both studies compared shortening of time to initiate enteral feedings after mNEC to a historical cohort. The cohort study Arbra, Oprisan, Wilson, Ryan, and Leshner (2018) is a retrospective cohort that evaluated patients with early or late feeding after mNEC. The data from Arbra et al. (2018) has been added to the meta-analysis in this synthesis (see Table 1 and Figure 2).

Variation in time to feeding. The included studies differed in the definition of early and late enteral feeding.

Study	Arbra et al. (2018)	Bohnhorst et al. (2003)	Brotschi et al. (2009)
Early Feedings	Feeds started < 7 days after diagnosis of NEC, <i>n</i> = 40	Feeds started after 3 days without evidence of gas bubbles in the portal vein, <i>n</i> = 26	Feeds started < 5 days after NEC diagnosis, <i>n</i> = 30
Dates collected	July 2006 to June 2016	January 1998 to December 2001	January 2000 to December 2006
Delayed Feedings	Feeds started ≥ 7 days after diagnosis of NEC, <i>n</i> = 98	Per the neonatologist, <i>n</i> = 18	Feeds started > 5 days after NEC diagnosis (median 5 days), <i>n</i> = 17
Dates collected	July 2006 to June 2016	April 1993 to March 1997	January 2000 to December 2006

### **Summary by Outcome**

**NEC recurrence.** Three studies (*n* = 229) measured NEC recurrence after early initiation of feeds after mNEC (Arbra et al., 2018; Bohnhorst et al., 2003; Brotschi et al., 2009). The studies reported the number of NEC recurrences as counts for early and late re-initiation of enteral feeding, and they are included in the meta-analysis (see Figure 2 and Table 1). The odds of NEC recurrence was not significantly different from restarting feedings later, *OR* = 0.46, 95% CI [0.15, 1.48].

**Certainty of the evidence for NEC recurrence.** The certainty of the body of evidence was very low based on four factors: *within-study risk of bias*, *consistency among studies*, *directness of evidence*, and *precision of effect estimates*. The body of evidence was assessed to have very serious risk of bias, very serious imprecision, not serious indirectness and serious inconsistency. Very serious risk of bias was assessed due to design, it is a cohort study, subjects were not randomized into feeding treatments, nor were subjects, providers, or outcome assessors blinded. Imprecision is serious due to the small number of subjects included in the papers. The studies are inconsistent in the definition of both early and late feeding. Furthermore, the date ranges from which the data was pulled was wide. For the Late Feeding group, data was pulled from 1993 to 2006. Time varying confounding occurs when

## **Office of Evidence Based Practice (EBP) – Critically Appraised Topic: Starting Enteral Feedings after Medical NEC**

the intervention received can change over time (Sterne, Higgins, & Reeves, 2014). Research published in the time between 1993 and 2006 may have suggested other changes in the care of the patient with mNEC that may have influenced the outcomes.

**Catheter related sepsis.** Two studies ( $n = 91$ ) measured catheter related sepsis (Bohnhorst et al., 2003; Brotschi et al., 2009). The studies reported results as counts of catheter related sepsis events, and they are included in the meta-analysis (see Figure 3 and Table 1). The odds of catheter related sepsis were not significantly different from restarting feedings later,  $OR = 0.2$ , 95% CI [0.01, 3.29].

**Certainty of the evidence for catheter related sepsis.** The certainty of the body of evidence was very low based on four factors: *within-study risk of bias*, *consistency among studies*, *directness of evidence*, and *precision of effect estimates*. The body of evidence was assessed to have serious risk of bias, very serious imprecision, not serious indirectness and serious inconsistency. Very serious risk of bias was assessed due to design, it is a cohort study, subjects were not randomized into feeding treatments, nor were subjects, providers, or outcome assessors blinded. Imprecision is serious due to the small number of subjects included in the papers. The studies are inconsistent in the definition of both early and late feeding. Time varying confounding occurs when the intervention received can change over time (Sterne et al., 2014). Research published in the time between 1993 and 2006 may have suggested other changes in the care of the patient with mNEC that may have influenced the outcomes.

**Intestinal stricture.** Three studies ( $n = 229$ ) measured intestinal stricture (Arbra et al., 2018; Bohnhorst et al., 2003; Brotschi et al., 2009). The studies reported results as counts of stricture occurrence, and they are included in the meta-analysis (see Figure 4 and Table 1). The odds of intestinal stricture were not significantly different from restarting feedings later,  $OR = 0.15$ , 95% CI [0.15, 2.37].

**Certainty of the evidence for intestinal stricture.** The certainty of the body of evidence was very low based on four factors: *within-study risk of bias*, *consistency among studies*, *directness of evidence*, and *precision of effect estimates*. The body of evidence was assessed to have very serious risk of bias, very serious imprecision, not serious indirectness and serious inconsistency. Very serious risk of bias was assessed because by design, it is a cohort study, subjects were not randomized into feeding treatments, nor were subjects, providers, or outcome assessors blinded. Time varying confounding occurs when the intervention received can change over time (Sterne et al., 2014). Research published in the time between 1993 and 2006 may have suggested other changes in the care of the patient with mNEC that may have influenced the outcomes.

Wu, Caplan, and Lin (2012)	Narrative review

**Methods Used for Appraisal and Synthesis**

<sup>a</sup>The [GRADEpro Guideline Development Tool \(GDT\)](#) is the tool used to create the Summary of Findings table(s) for this analysis.

<sup>b</sup>Rayyan is a web-based software used for the initial screening of titles and / or abstracts for this analysis (Ouzzani, Hammady, Fedorowicz & Elmagarmid, 2017).

<sup>c</sup>The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) flow diagram depicts the process in which literature is searched, screened, and eligibility criteria is applied (Moher, Liberati, Tetzlaff, & Altman, 2009).

<sup>d</sup>Review Manager (Higgins & Green, 2011) is a Cochrane Collaborative computer program used to assess the study characteristics as well as the risk of bias and create the forest plots found in this analysis.

91 (2 Cohort)	serious <sub>a,b</sub>	serious <sub>c,d</sub>	not serious	very serious <sub>d</sub>	none	⊕○○○ VERY LOW	10/35 (28.6%)	5/56 (8.9%)	<b>OR 0.20</b> (0.01 to 3.29)	286 per 1,000	<b>212 fewer per 1,000</b> (from 282 fewer to 283 more)
<b>Intestinal Stricture</b>											

**Office of Evidence Based Practice (EBP) – Critically Appraised Topic:  
Starting Enteral Feedings after Medical NEC**

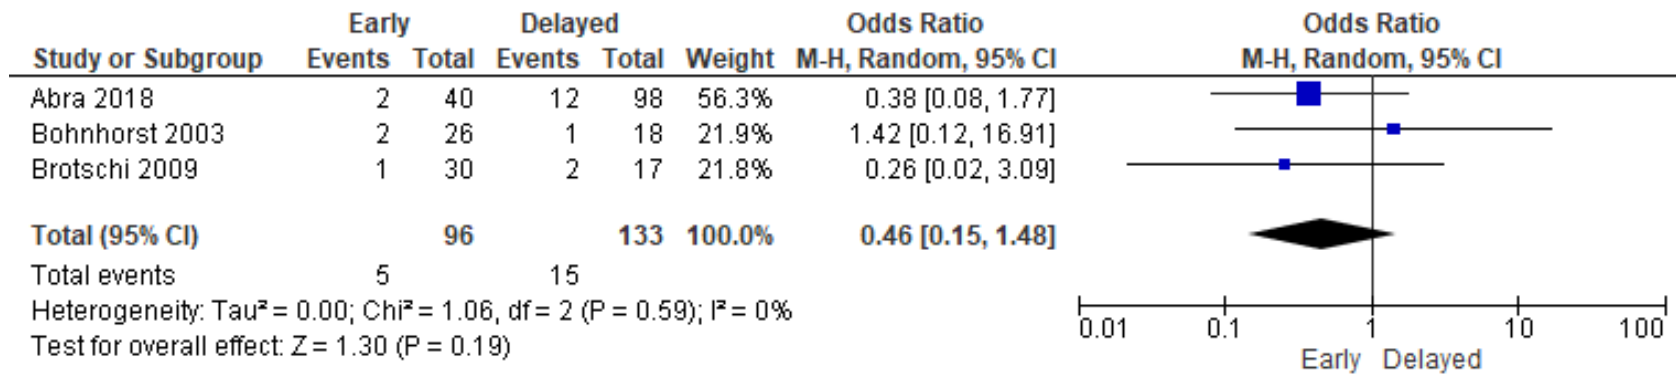

Certainty assessment						Summary of findings					
229 (3 cohort)	serious <sup>a,b</sup>	serious <sup>c,d</sup>	not serious	very serious <sup>d</sup>	none	⊕○○○ VERY LOW	6/133 (4.5%)	3/96 (3.1%)	<b>OR 0.59</b> (0.15 to 2.37)	45 per 1,000	<b>18 fewer per 1,000</b> (from 38 fewer to 56 more)

CI: Confidence interval; OR: Odds ratio

**Notes:**

- a. It is a cohort study, by design, so it starts at lower level of evidence.
- b. Time varying confounding, which is a selection bias occurs due to the wide range of dates in which subjects were enrolled
- c. The definition of early and late feeding varied among the studies.
- d. Low number of studies that include a low number of subjects.

<i>Characteristics of Study</i>	
<b>Design</b>	<b>Quantitative Synthesis (meta-analysis)</b>
<b>Objective</b>	Determine if timing of the initiation of enteral feedings after an episode of Bell stage II NEC influenced the recurrence of NEC
<b>Methods</b>	<p><b>Protocol and registration.</b></p> <ul style="list-style-type: none"> <li>• Not reported</li> </ul> <p><b>Eligibility Criteria.</b></p> <ul style="list-style-type: none"> <li>• Human studies</li> <li>• Assessed the timing of feeds after medical NEC             <ul style="list-style-type: none"> <li>◦ Early – starting feeds &lt; 5 days (median)</li> <li>◦ Late – starting feeds &gt; 5 days (median)</li> </ul> </li> <li>• Primary outcome was recurrence of NEC</li> </ul> <p><b>Exclusion criteria</b></p> <ul style="list-style-type: none"> <li>• Feeding protocol was unclear</li> <li>• Timing of starting feeds after mNEC was unclear</li> <li>• Overlap of data form a study in the same center</li> </ul> <p><b>Information sources.</b></p> <ul style="list-style-type: none"> <li>• MEDLINE 1966 to November 2016</li> <li>• EMBASE 1947 to November2016</li> <li>• Google Scholar</li> <li>• Cochrane database</li> </ul> <p><b>Search</b></p> <ul style="list-style-type: none"> <li>• feed OR feeding AND necrotizing enterocolitis</li> </ul> <p><b>Study Selection.</b></p> <ul style="list-style-type: none"> <li>• Two authors independently screened, extracted, and analyzed the studies and gave reasons for excluding studies.</li> <li>• All authors achieved consensus when faced with disagreements</li> </ul> <p><b>Data collection process.</b></p> <ul style="list-style-type: none"> <li>• A spreadsheet was designed to collect the following information: study characteristics, criteria for diagnosing NEC, study design, feeding protocols, and outcomes.</li> </ul> <p><b>Risk of bias (RoB) across studies.</b></p> <ul style="list-style-type: none"> <li>• The Newcastle-Ottawa scale was employed</li> </ul> <p><b>Summary measures.</b></p> <ul style="list-style-type: none"> <li>•</li> </ul> <p><b>Synthesis of results.</b></p> <p>RevMan 5.3 to calculate pooled odds ratios with 95% confidence intervals. If the I<sup>2</sup> was &lt; 25% a random effects model was used, if ≥ 25% a random effects model was employed.</p>
