Background
Vaso-occlusive episode (VOE) is the most common acute complication for individuals with sickle cell disease (SCD) and the most common reason to seek medical care. Recommendations are rapid initiation of analgesia therapy upon arrival to emergency department (ED) with timely subsequent doses given as needed for pain.

- At Children’s Mercy Hospital (CMH), recommendation is initial intravenous (IV) dose of analgesia within 60 minutes of registration and subsequent doses every 20 minutes as needed for pain.
- If patient is determined to need admission for further pain management, goal at CMH is to initiate continuous infusion (CI) of pain medication within 60 minutes of last bolus dose of pain.
- At CMH, a delay in initiation of analgesia therapy upon arrival to ED as well as delay in initiation of CI of pain medication has been observed (Figure 1).
- Delays in medication administration lead to poor pain control.

Aim Statements
By December 2018, reduce time to <60 minutes in patients with SCD presenting to ED with VOE for:
1. Time interval between registration and 1st dose of pain medication in 80% of patients.
2. Time interval between 1st and 3rd dose of pain medication in 80% of patients.
3. Time interval between initiation of continuous infusion of pain medication and 3rd dose of pain medication in 60% of patients.

Results
- Baseline data was obtained by retrospective chart review over a three month period, represented on Figures 2, 3, and 4.
  - A median of 58.8% of patients were receiving an initial dose of analgesia therapy within 60 minutes of registration.
  - Thirty-six minutes between first and third dose occurred in 53.8% of patients.
  - Initiation of CI was occurring in 8.3% of patients within 60 minutes of the third dose of opioids.
  - Over the first three PDSA cycles (June 2018 – August 2018), improvement has been noted across all 3 aims.
    - For the initial dosing, all 3 months were above baseline with one month reaching target at 80%.
    - For time-between first and third dose of pain medication, 2 of 3 months were above baseline.
    - For time-between third dose and initiation of CI, all 3 months were above baseline.

Conclusions and Future Direction
- Improved efficiency in time to initiation of analgesic support has been shown to lead to improved pain management in patients with SCD presenting to the ED for VOE.
  - It is anticipated that with the eventual achievement of the aims, a decreased admission rate will be noted.
  - For those individuals still requiring further analgesic support, it is felt faster initiation of CI will lead to quicker control of VOE and, subsequently, shorter hospitalizations.
  - Integration of process measures into PP will allow for sustainable improvement/development of new standard.
    - Monitoring qualitative results will allow for identification of when PP not working has failed.
  - Additional countermeasures are currently being vetted in anticipation to adding to the current interventions to further improve the project’s efforts and maintain the long-term success of this project over time.
    - Plan will be to continue to run monthly PDSA cycles for a total of 6 months to evaluate response of timing to initial adjustments before integrating further interventions.
    - At completion of a 12 month period of monthly data collection, data collection and review will then be done quarterly.
    - Presented at quarterly Hematology/Oncology/ED meetings.
    - Qualitative data will also be discussed to ensure continued improvement established by current project.
