Evaluation of the hypothesis that viral meningitis can mimic abusive head trauma
Danielle Horton MD; Tanya Burrell MD; Mary Moffatt MD; Henry Puls MD; Raj Selvarangan PhD; James Anderst MD MS

Children’s Mercy Hospital Kansas City

Results – Demographics Domain

- N = 397 VM subjects, 118 AHT proxy subjects and 35 SDH only subjects
- AHT and SDH only subjects were significantly older than VM subjects
- AHT subjects were more likely to be male, minority race and publicly insured than VM subjects

Results – History Domain

- Symptoms of neurologic compromise common in AHT and SDH only subjects
- AHT (OR 322.5 [121.0-859.3]) and SDH only subjects (OR 485.2 [63.8-3686.5]) were significantly more likely than VM subjects to have a history of no fever
- AHT and SDH only subjects were more likely to have vomiting than VM but less likely to have other ill symptoms

Results – Clinical Domain

- Higher odds of intubation (OR 62.4 [18.8-207.1]), witnessed seizure (OR 10.2 [3.9-26.8]) in AHT subjects compared to VM
- Significantly higher odds of intubation (OR 12.3 [2.4-63.5]) in SDH only subjects compared to VM
- VM subjects more likely than AHT and SDH only subjects to have a clinical fever
- SDH only subjects less likely to be intubated and have witnessed seizure than AHT

Background

- Viral meningitis (VM) has been proposed to mimic abusive head trauma (AHT)
- Comparing VM and AHT across presenting features will evaluate this theory
- Hypothesis: VM will differ significantly from AHT in historical and clinical presenting features
- Objectives: Compare VM to AHT proxy group across demographic, HPI and clinical domains. Compare both groups to SDH only

Objectives/Methods

- Retrospective, case-control study of subjects < 24 months old
- VM subjects: CSF positive for PeV, EV or HSV
- Subjects with CAP consultation had SDH identified by CT or MRI brain
- Concomitant suspicious injuries (CSIs) used to categorize SDH subjects into “AHT proxy” and “SDH only” groups

Conclusions

- Viral meningitis is not supported as a mimic of abusive head trauma
- AHT subjects are more ill appearing than VM
- SDH subjects are more similar to AHT subjects than VM subjects in historical features
- Certain combinations of features have a high PPV for abuse
